

UNIVERSAL AI PROJECT BRAIN SETUP

First, deeply analyze the entire project before creating or changing anything.

Understand:

- project structure and architecture
- frontend/backend/services
- database and data flow
- APIs and integrations
- authentication/authorization
- environment/configuration
- deployment setup
- important workflows and dependencies
- existing documentation
- current implementation state
- known bugs, limitations, and technical debt

CRITICAL RULES

1. DO NOT modify, refactor, delete, rename, move, or rewrite any existing source code.
2. DO NOT change configuration, dependencies, environment files, database schemas, APIs, UI, or behavior.
3. DO NOT fix issues during this task.
4. DO NOT assume or invent project information.
5. Only create the documentation files inside:
"ai/"
6. If something cannot be verified from the project, explicitly mark it as UNKNOWN / NOT VERIFIED.
7. Preserve all existing project behavior exactly as it is.
8. Before writing the documentation, inspect the actual project so these files represent the current reality, not assumptions.

CREATE

ai/

```
|— instructions.md  
|— decisions.md  
|— known-issues.md  
|— current-state.md
```

1. "ai/instructions.md"

Document instructions that future AI agents must follow while working on this project.

Include:

- project-specific rules
- architecture constraints
- coding conventions discovered from the project
- files/modules that require extra caution
- things that must not be changed without approval
- testing/validation expectations
- deployment/release precautions
- security-sensitive areas
- user approval requirements
- important project-specific context

Do not invent rules. Clearly distinguish existing project conventions from recommended rules.

2. "ai/decisions.md"

Create a chronological record of important technical decisions already present in the project.

For each decision, document:

- Decision
- Why it appears to have been made
- Current implementation
- Files/components affected
- Known trade-offs
- Evidence/source in the project
- Whether the reason is verified or inferred

Do not rewrite history or invent the reasoning behind decisions.

3. "ai/known-issues.md"

Document currently discovered problems and risks.

Include:

- bugs
- broken or incomplete functionality
- technical debt
- security concerns
- performance concerns
- reliability issues

- inconsistent behavior
- missing validation
- dependency/integration risks
- deployment issues
- documentation gaps

For every issue include:

- Issue
- Severity
- Evidence
- Affected area
- Current behavior
- Expected behavior, if verifiable
- Possible impact
- Status
- Recommended next investigation/fix

Do not fix anything.

4. "ai/current-state.md"

Create a factual snapshot of how the project currently works.

Include:

- project purpose
- technology stack
- architecture
- directory structure
- major components
- frontend flow
- backend flow
- database structure
- API structure
- authentication/authorization
- external services
- environment/configuration
- build/run process
- deployment setup
- important workflows
- current feature status
- dependencies
- known limitations

Focus on what exists today, not what the project should become.

FINAL VALIDATION

Before finishing:

- Verify all four files against the actual project.
- Remove assumptions presented as facts.
- Mark unverified information clearly.
- Ensure documentation does not contradict the code.
- Ensure NO existing source-code files were modified.
- Ensure the task only created/updated the "ai/" documentation requested above.

Finally, provide a concise report containing:

1. Project areas analyzed
2. Files created
3. Important findings
4. Unverified/unknown areas
5. Confirmation that no existing source code was modified
6. Recommended next audits — without performing them
